ABSTRACT

Background: Leukemia is a group of blood cancers that usually begin in the bone marrow and result in high numbers of abnormal blood cells. These blood cells are not fully developed and are called blasts or leukaemia cells.

Aim of Work: Our study aimed to evaluate bone density by DXA scan in children and adolescents with Acute Lymphoblastic leukaemia at diagnosis and after 6 m of treatment with chemotherapy.

Subject and Methods: The study was conducted in the Pediatric Department Hematology and Oncology Unit of Tanta University and Tanta Cancer Center, From November 2020 to November 2022.

Study Subjects: Evaluation of Bone Mass Density in Children and Adolescents with Acute Lymphoblastic Leukemia.

*Corresponding author: Email: Omniaazzam2020@gmail.com;

Study design: observational cross-sectional. This study included 25 children diagnosed with Acute Lymphoblastic Leukemia (the same 25 Patients were examined at diagnosis and after 6 months of treatment with chemotherapy).

Results: The mean age of this study children was 7.92+ 3.59 years in group I and 8.42+ 3.59 years in group II. The two groups were matched as regards weight, Height, and BMI.

In the present study, Bone Mass Density was significantly lower in the leukaemia children after 6 months of treatment of chemotherapy (0.53±0.11), compared to leukaemia children at the time of diagnosis (0.59±0.11) (P<0.05). Also, bone mineral content and Z score were significantly lower in group II patients (20.5±7.82 and 1.120±0.37, respectively), compared to group I (23.13±9.18 and 2.25±0.45, respectively).

Conclusion: Bone Mass Density, bone mineral content and Z score are significantly lowered after chemotherapy of ALL patients. Since a reduced BMD predisposes to osteopenia and osteoporosis, the use of DXA scanning to evaluate and monitor BMD in children with ALL may be useful to identify those patients at risk for developing osteopenia, osteoporosis, and pathological fractures.

Keywords: Bone mineral density; dual-energy X-ray absorptiometry; acute lymphoblastic leukaemia.

1. INTRODUCTION

“Leukaemia is a group of blood cancers that usually start in the bone marrow and lead to large numbers of abnormal blood cells. These blood cells are not fully developed and are called embryonic white blood cells” [1]. “Damage to the bone marrow, by replacing normal bone marrow cells with a higher number of immature white blood cells, leads to a lack of blood platelets, which are important in blood clotting, and cells red blood cells lead to anaemia. Diagnosis is usually made by blood tests or bone marrow aspiration” [2]. “Factors that can increase your risk of developing certain types of leukaemia, include previous cancer treatment, genetic disorders, exposure to certain chemicals, smoking, and a family history of leukaemia bridge” [3]. “Leukaemia symptoms vary, depending on the type of leukaemia. Common leukaemia signs and symptoms include fever or chills, persistent fatigue, weakness, frequent or severe infections, loss of weight swollen lymph nodes, enlarged liver or spleen, easy bleeding or bruising, recurrent nosebleeds, petechiae, excessive sweating, especially at night, bone pain or tenderness, skeletal abnormalities are commonly seen in children and adolescents with leukaemia” [4].

Bone growth in length is not altered at leukaemia diagnosis, as absolute height in children with leukaemia is not different from healthy children. However, bone density at leukaemia diagnosis is altered before initiating chemotherapy.

“At diagnosis, serum markers of bone formation, including osteocalcin, the carboxyl-terminal

property of type I collagen, and bone-specific alkaline phosphatase, were low. Several studies have shown abnormally low levels of 1,25-dihydroxycholecalciferol or 1,25-dihydroxy vitamin D3, hypercalciuria, low parathyroid hormone, and low to normal levels of calcium, magnesium, and phosphate” [5].

During Acute lymphoblastic leukaemia treatment, bone formation and resorption markers are increased resulting in a decrease in total body Bone mass density (mean -0.68, SD 1.26) within the first six months of treatment.

“Lower Bone mass density at diagnosis is associated with a higher prevalence of subsequent bony fractures during Acute lymphoblastic leukaemia therapy, low lumbar spine Bone mass density at diagnosis and during treatment should be used to identify Acute lymphoblastic leukaemia patients at significant risk for bony fractures and osteoporosis” [6]. Poor nutrition, low vitamin D, and poor muscle mass contribute to the development or worsening of bone pathology during therapy that may result in osteoporosis, fracture, and Osteo necrosis. Endocrine abnormalities further contribute to bone morbidity. Bone mass density is measured by Dual-energy X-ray absorptiometry (DXA).

1.1 Aim of the Work

This work aims to evaluate bone density by DXA scan in children and adolescents with Acute Lymphoblastic leukemia at diagnosis and after 6 months of treatment with chemotherapy.

2. PATIENTS AND METHODS

2.1 Study Area Setting

The study was conducted in the Pediatric Department Hematology and Oncology Unit of Tanta University and Tanta Cancer Center, From November 2020 to November 2022.

2.2 Study Subjects

Evaluation of Bone Mass Density in Children and Adolescents with Acute Lymphoblastic Leukemia

2.3 Study Design

observational cross-sectional.

This study included 25 children diagnosed with Acute Lymphoblastic Leukemia (the same 25 Patients were examined at diagnosis and after 6 months of treatment with chemotherapy).

Individuals enrolled in this study are divided into:

- **Group (I):** 25 Children and Adolescents with Acute Lymphoblastic Leukemia at the time of diagnosis
- **Group (II):** 25 Children and Adolescents with Acute Lymphoblastic Leukemia after 6 months of treatment with chemotherapy (1).
- **Inclusion criteria:** Children and adolescents diagnosed with acute lymphoblastic leukemia, aged 2-18 years (Inaba and Pui, 2021). Blast cells in bone marrow aspiration were >20%.

2.4 Exclusion Criteria

- I- Other types of malignancy.
- II- Acute Lymphoblastic Leukemia with hyperleukocytosis

2.5 Methods

2.5.1 All children in this study were subjected to the following

1- History taking

History of age of onset, symptoms, signs, medical history and family history

2-Thorough clinical examination

3- Laboratory investigations: Routine investigation:

1-Complete blood count

2- Renal function tests

3- Liver function tests

4- Bone marrow aspiration.

5-Calcium panel: ionized calcium

6-Phosphorous

7-Magnesium

8- Alkaline phosphatase.

2.6 Specific Investigation

1-Parathermone hormone

2-DXA scan (Madix90 IMD Generators S.R.L 2016) at diagnosis and 6 Months later after starting chemotherapy

Privacy of all data was guaranteed as follows:

- Every patient had a code number. The name and the address were kept in a special file.
- The results of the study were used only for scientific purpose and wasn't used for any other purposes.

2.7 Risks on the Participants in this Study and how to Manage

2.7.1 The risks to Participants and measures used to minimize these risks

No risks documented but unexpected risks that may occur during the research will be cleared to the participants and ethical committee on time.

The adequate provisions to maintain the privacy of participants and the confidentiality of data are as follows:

A special file was created to mark the patient code numbers in it.

- A code number has been placed for each patient, a code for the name and address
- The patient's name has been hidden when using the search.
- The results of the research were used for the scientific purpose only.

2.8 Statistical Evaluation

Statistical presentation and evaluation of the prevailing look at become conducted, the usage of the mean, general deviation a look at through SPSS V.22.

1 - Student t-test:

For normally distributed quantitative variables, to compare between two studied groups.

2 - Mann Whitney test:

For abnormally distributed quantitative variables, to compare between two studied groups.

3 - F-test (ANOVA)

For normally distributed quantitative variables, to compare between more than two groups.

4 - Pearson coefficient

To correlate between two normally distributed quantitative variables.

3. RESULTS AND DISCUSSION

As regards Bone Mass Density, Bone Mineral content and Z score were significantly lower in the patient Group (II) compared to Group (I), ($P < 0.05$).

Z score (Lumbar spine) Group (I) was in the normal range (> -1) However in some patients BMD was mildly decreased but still in a normal range. Z score (Lumbar spine) Group (II) (56%) was in the normal range (> -1), (40%) was osteopenia (-1 to -2) and (4%) was Osteonecrosis (< -2).

Table (4) and Fig. 4. show that: According to Total leucocyte count was significantly lower in the patient Group (II) compared to Group (I), ($P < 0.05$).

There was no significant difference between 2 groups in this Variable (Hemoglobin, Platelet, Hematocrit, mean corpuscular volume, Mean corpuscular haemoglobin, mean corpuscular haemoglobin concentration and Red cell distribution width - coefficient of variation) $P > 0.05$

Table (5) and Figs. 6,7. show that: There were no significant differences in Calcium, ionized calcium, parathyroid hormone and Magnesium among the studied groups ($P > 0.05$). However, Phosphorus and Alkaline phosphatase were significantly lower in the patient Group (II) compared to Group (I), ($P > 0.05$).

There were significant differences in Alkaline phosphatase among the studied groups ($P < 0.05$).

“Acute lymphoblastic leukaemia (ALL) is the most common cancer among pediatric and adolescent patients, and it accounts for major cancer-related deaths in childhood” [7].

“Despite advances in management, the backbone of therapy remains multi-agent chemotherapy with vincristine, corticosteroids and an anthracycline with allogeneic stem cell transplantation for eligible candidates” [8].

“Administration of chemotherapeutic agents destroys bone formation. Among current regimens of chemotherapy against ALL, osteotoxic drugs such as glucocorticoids, methotrexate, L-asparaginase, daunorubicin, and vincristine, as well as irradiation treatment, are predominant risk factors that equally cause deficient BMD” [9].

“Despite direct leukemic effects and exposure to multiple osteotoxic treatment regimens, which altogether induce demineralization, the most rapid skeletal development occurs during childhood and adolescence. Skeletal recovery after therapy completion in children with ALL is crucial, while bone metabolic status continues to change significantly in this age group. Survivors begin to recover lost bone mass after ALL therapy, while those who do not reach their optimal bone mineral acquisition experience critical bone loss 2 years following therapy cessation” [10].

The current study included 25 children and adolescents; 25 children and Adolescents with Acute Lymphoblastic Leukemia at the time of diagnosis (Group I) and 25 children with leukaemia after 6 months of treatment of chemotherapy (Group II). The mean age of this study children was 7.92 ± 3.59 years in group I and 8.42 ± 3.59 years in group II. The two groups were matched as regards weight, height and BMI.

In the present study, Bone Mass Density was significantly lower in the leukaemia children after 6 months of treatment of chemotherapy (0.53 ± 0.11), compared to leukaemia children at the time of diagnosis (0.59 ± 0.11) ($P < 0.05$).

“In agreement with the present study Boot et al. reported that at diagnosis, 3 of 14 (21%) children with ALL had a low lumbar spine BMD. Markers of bone turnover were reduced. Total body BMD decreased during the first year of treatment, suggesting a negative effect of chemotherapy or

other factors like decreased physical activity on cortical bone” [11].

In contrast, Cox et al. stated that “there were no significant changes between patients who

received chemotherapy and the control group in BMD at the end of treatment”. “While BMD declined in both the intervention and the control group, rates of decline did not differ between groups (P = 0.56)” [12].

Table 1. Comparison between the two groups as regards BMD, BMC and Z scores

Cases
Normal cases Z score >-1
Case 1

Picture 1. SAMA scan at the time of diagnosis (Z score >-1)

Picture 2. SAMA scan after 6 months of treatment with chemotherapy (Z score >-1)

In the current study, bone mineral content and Z score were significantly lower in group II patients (20.5±7.82 and 2.1120±0.676, respectively), compared to group I (23.13±9.18 and 82.25±85.2, respectively). Z score (Lumbar spine) of all group I children and Adolescents with ALL at the time of diagnosis was in the normal range (>-1). While 56% of group II children had a normal Z score (Lumbar spine) range, 40% had Osteopenia (-1 to-2) and 4% had osteonecrosis (< -2).

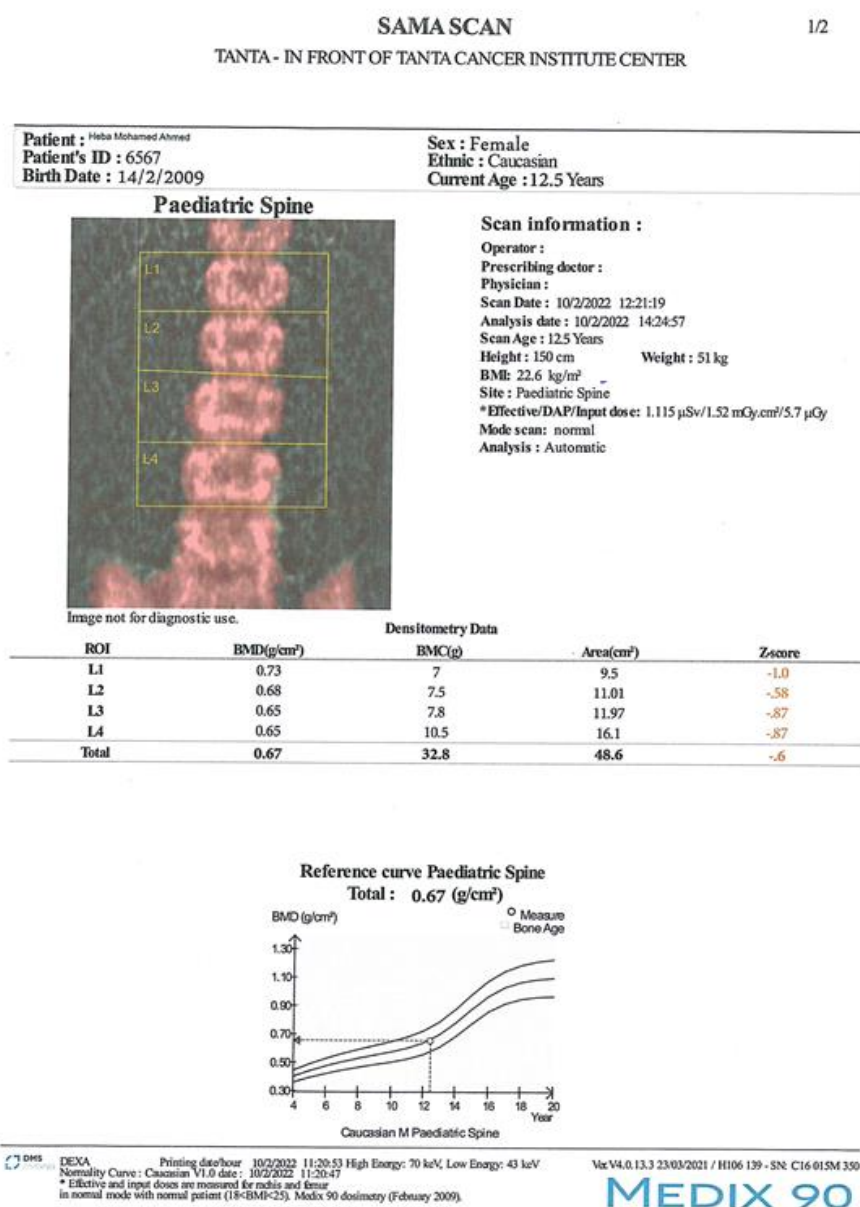

“In concordance with the current study, Inaba and colleagues detected that the median BMD Z-score in 363 ALL patients was 0.06 at

diagnosis, declined to -1.08 at week 120, but partly recovered to -0.72 after 2 years off therapy” [13].

In concordance with this study, Aricò et al. reported that among ALL children who received chemotherapy Overall, 15 of the 1421 patients developed symptomatic ON (1.1%) [14].

Dolu and colleagues in their study stated that “a total of 18.66% (14 patients) of patients were osteoporotic (z score <-2 SD), 22.67% (17 patients) were osteopenic (z-score between -2 and -1 SD) and 58.67% (44 patients) presented normal z-scores (>-1 SD)” [15].

Case of osteopenia Z score (-1 to -2) Case 1

Picture 3. SAMA scan at the time of diagnosis Z score (-1 to -2)

Also, supporting this study, Athanassiadou and colleagues' data demonstrate that "bone metabolism in children with ALL during consolidation therapy is disturbed, resulting in a reduced BMD and z-score concerning healthy controls" [16].

In this study children with leukaemia after 6 months of treatment of chemotherapy had significantly lower Total leucocyte count (2.1120 ± 0.676), compared to children and adolescents

with Acute Lymphoblastic Leukemia at the time of diagnosis (82.25±85.2).

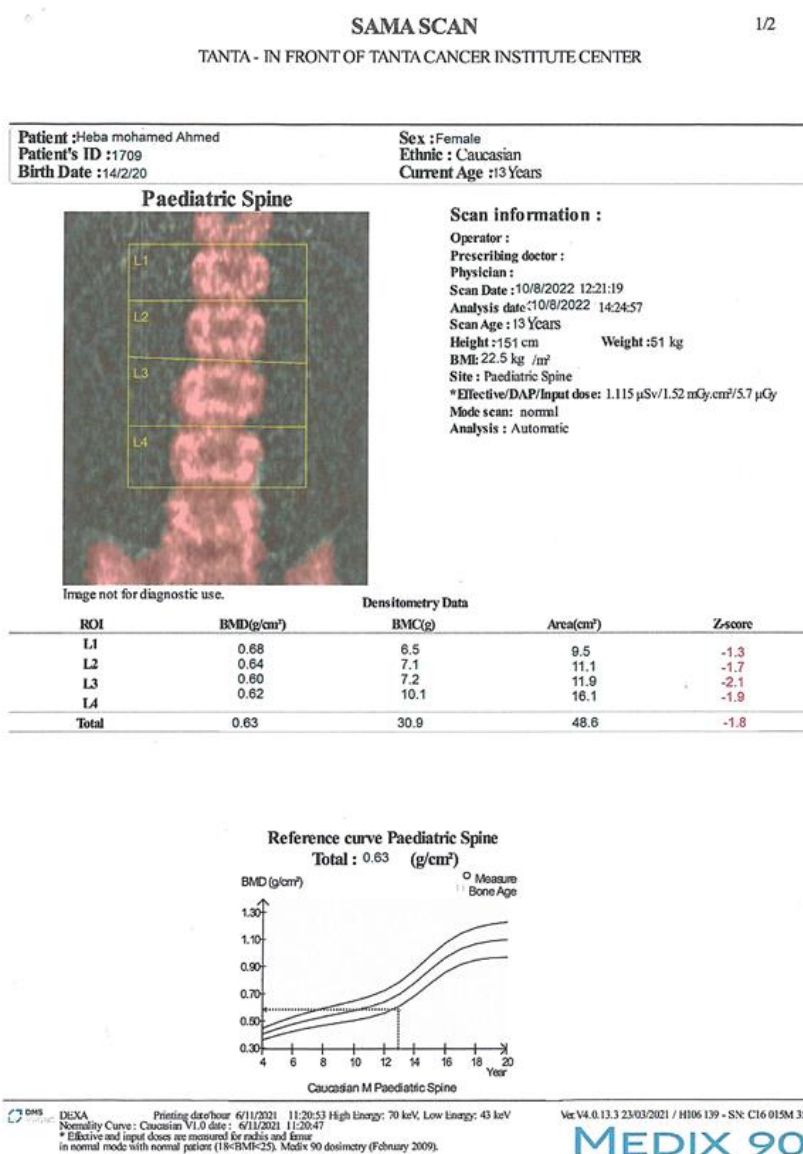

There was no significant difference between the 2 groups included in this study, regarding haemoglobin, platelet, hematocrit, mean corpuscular volume, mean corpuscular haemoglobin, mean corpuscular haemoglobin concentration and red cell distribution width - coefficient of variation.

There was no significant difference according to Serum Glutamic Pyruvic Transaminase, and serum glutamic-oxaloacetic in the patient Groups (II): Children with leukaemia after 6 months of treatment of chemotherapy compared to Group (I): Children with leukaemia at the time of diagnosis ($P>0.05$). However, AL-JUMAILI and coworkers in their study detected significantly higher AST and ALT levels among ALL children receiving chemotherapy [17].

“Creatinine is commonly used as a measure of kidney function. The diagnosis of renal failure is often suspected when serum creatinine is greater than the upper limit of the normal interval. The

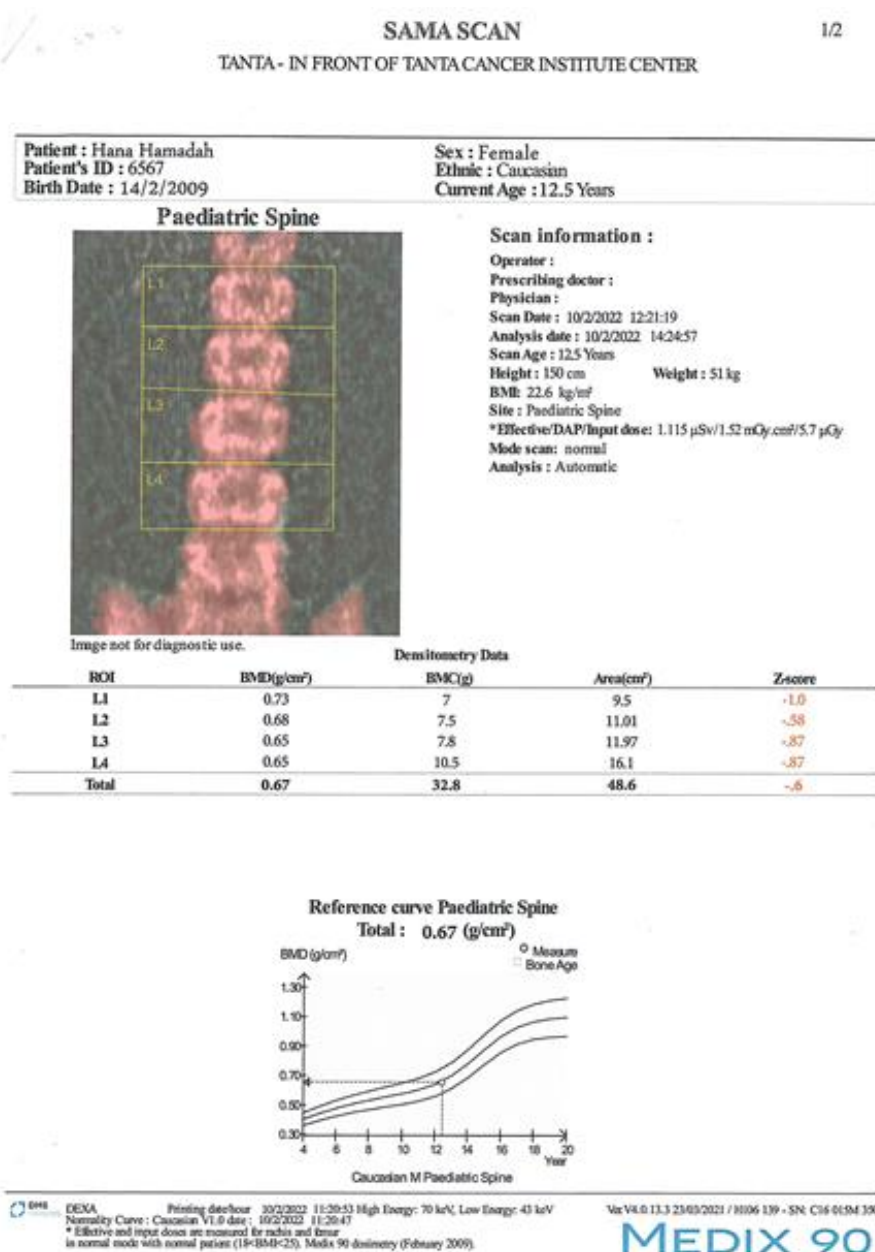

higher values are noticed in leukaemia” [18]. This can explain the high creatinine values both at diagnosis and after 6 months of treatment.

In the present study the mean alkaline phosphatase level in children with leukaemia after 6 months of treatment of chemotherapy was significantly lower (107.88 ± 11.59), compared to Children with leukaemia at the time of diagnosis (161.52 ± 3.66). Also, Phosphorus was significantly lower in the patient Group (II) compared to Group (I) ($P>0.05$). However, there were no significant differences in calcium, ionized calcium, parathyroid hormone and magnesium among the studied groups ($P>0.05$).

Picture 4. SAMA scan after 6 months of treatment with chemotherapy Z score (-1 to -2)

Case of osteonecrosis Z score <-2 Case 1

Picture 5. SAMA scan at the time of diagnosis (Z score <-2)

Crofton et al. studied “bone turnover and growth during and after continuing chemotherapy in children with acute lymphoblastic leukaemia”. “It was found that the second year of continuing chemotherapy in children with ALL was associated with reduced bone ALP, which suggests impaired osteoblast development and reduced mineralization of bone. After completion of treatment, bone ALP was restored to normal” (Crofton et al. 2000).

Similarly, Asadi et al had studied “20 patients aged 8 + 2.4 years. Average serum calcium levels were 9 mg/dl before chemotherapy and 9.4 mg/dl after chemotherapy. Differences in phosphorous and alkaline phosphatase were not significant. Sixty-five percent of patients had hypercalciuria before chemotherapy, but it has decreased subsequently”. “It seems that disturbances of mineral and especially calcium metabolism are common in ALL patients.

Chemotherapy has not been found to have a considerable effect on calcium mineral levels rather it appears that induction chemotherapy controls the disease process with a reduction of hypercalcemia" [19].

Moreover, in Turkey's survey, levels of ALP, phosphorus, calcium, magnesium, 25-hydroxy vitamin-D and IGF-1 were assessed at the end of treatment in children (n=70) whose IGF 1 and 25-hydroxyvitamin D were reported lower than

control group (p=0.033) (Gunes et al. 2010) Compared with our study included 25 children with ALL, the amounts of Ca, P, PTH and ALP were in normal range.

In contrast, Halton et al. reported that "among ALL patients, normal plasma magnesium and ionic calcium were observed at diagnosis, but by 6 months on therapy, 84% of children had become hypomagnesemic" [20].

Picture 6. SAMA scan after 6 months of treatment with chemotherapy (Z score <-2)

According to this study's results, there was a significant correlation between BMD with age, BMC, and SGOT ($P = 0.001$). Also, There was a significant correlation between the Z score with all Variable and age, BMC, sex and BMD ($P = 0.001$).

Ghasemi et al. reported contradicting results with the present study where there was no significant difference in BMD after chemotherapy between the sexes among ALL patients [21].

4. CONCLUSION

After ALL patients get chemotherapy, Z score, bone mineral content, and bone mass density all markedly decline. The use of DXA scanning to test and monitor BMD in children with ALL may be beneficial to identify those patients at risk for developing osteopenia, osteoporosis, and pathological fractures because a lower BMD predisposes to both conditions.

CONSENT

Informed consent was obtained from all patients after a full explanation of the benefits and risks of the study.

ETHICAL APPROVAL

As per international standard or university standard written ethical approval has been collected and preserved by the author(s).
